Abstract: This paper has mainly analyzed the characteristic of AUTOSAR NM (Network Management) mechanism, and combined with the FlexRay communication network’s requirements of vehicle motor drive system, Designed the FlexRay NM control strategy, NM message, time parameters, and built a simulation and hardware in the loop platform to verify these design, the results show it can meet with the network nodes of electric vehicle motor drive system control’s requirements. Keyword: Network management, FlexRay, Four-wheel drive control system.

1. Introduction

Recently, with the development of electronic technology, the electronic control unit (ECU) has been applied to vehicle distributed control system widely, and it becomes more and more complex, the information that exchanged between the ECUs has become huge. The vehicle networks (such as CAN, LIN, MOST) have been applied to vehicle electronic control system widely. Nowadays, the networks that mentioned above cannot satisfy the demand of the complex vehicle electronic control system.

Therefore, many universities and research institutions have studied new vehicle network and control strategies, such as the TTCAN enhances the periodic signal processing capability [1], the Time-Triggered Protocol (TTP) [2], the wireless sensor networks instead of the other network [3, 4], which cannot resolve all the automotive network management problems.

Finally, the FlexRay network protocol that formulated by FlexRay Union established by many automobile companies is recognized by the automotive industry, and then become the next generation main control network of vehicles, to meet the requirements of vehicle control.

FlexRay standard [5] defines the basic protocol, such as frame structure, the frame synchronization and other requirements, including the FlexRay static state feature [6] and dynamic feature [7] in the transmit processing. But there are few papers about the nodes’ network management (NM) in the FlexRay network. Only few suggestions we can get from several papers about the OSEK/VDX NM protocol [8], implemented on dynamic segment of the FlexRay communication cycle.
FlexRay communication protocol is triggered based on time, a communication cycle period includes static section, dynamic section, symbol window, network idle time. Its static segment uses TDMA (Time Division Multiple Access) access method, every node in the network occupies specified static slot to transmit the message, to guarantee each node send message in static segment which has a certain time. The dynamic segment takes the FTDMA (Flexible Time Division Multiple Access) method to visit, non-periodicity signal is sent in dynamic segment. While the node inquires to send message, it occupies one or more mini slot to send dynamic message.

The OSEK/VDX NM standard is a widely vehicle network management protocol[9], it suits for event trigger network, the NM statement transform is based on the timer in the node, the NM messages are sent with uncertainty, it mainly applies to the CAN (Controller Area Network), doesn’t suit for the FlexRay network which is based on the time trigger. In the FlexRay communication network, the network communication cycle, static frame, dynamic frame are associated with NM messages and NM states, these are not well achieved on the OSEK/VDX NM.

AUTOSAR (Automotive Open System Architecture) alliance published AUTOSAR FlexRay NM in 2008. AUTOSAR FlexRay NM[10] fully is considered the characteristics of the FlexRay network, and it can reach the demand of high speed and deterministic communication needs.

This paper’s research focuses on the FlexRay communication NM, which is mainly based on the AUTOSAR NM protocol.

2. FlexRay Network Management Principle

AUTOSAR FlexRay NM is implemented by the periodicity NM message, network state transform is based on the node’s inquire network state and periodicity NMPDU (Network Management Protocol Data Unit), NM cycle synchronies the FlexRay communication cycle periodicity.

According to the AUTOSAR FlexRay network manage state transfer, the FlexRay communication network and FlexRay NM state transfer, show in Fig. 1.

2.1 NM Algorithm

AUTOSAR NM takes the distributed directly NM mechanism [11], each node can receive and send message by independent NM, the network state transfer is based on the node require network state and periodicity NMPDU is received. A node that receives a broadcast NMPDU indicates that the node which sends message is intention to keep network wakeup state. If one node prepares to enter the bus sleep state, then it stop to send NMPDU, but if it receives NMPDU from others, it can postpone network sleep state transfer. If the node can not receive the NMPDU, the preset time (FlexRay communication period counter) would be overflowed, therefore the node can enter the bus sleep state. If the node needs to communicate with others, it should send NMPDU to wake up network from the sleep state to normal state.

![Fig. 1. State transfer and condition.](image-url)
2.3. The Node Online Monitor

When some node needs to monitor other node which is online or not (generally the node can generate a RepeatMessage requirement), this node’s network state will transfer to Ready-Sleep mode, and then send the RptMsgRequest. If the receive node NM state is Normal Operation or Ready-Sleep, when it received RptMsgRequest this node NM state will transfer to RepeatMessage mode and send NM message periodically. Sending the “periodical NM message (RptMsgRequest)” by read the NM-Data from other node in the network to judge which node is online.

Some nodes monitor other node which is online in the network, the algorithm show in Fig. 2.

![Fig. 2. The algorithm that the node online monitor](image)

2.4 Node Synergy Sleep

The node transfers the state from the Ready-Sleep to Sleep mode, it can initialize Sleep counter FrNmReadySleepCnt, meanwhile the counter will decrease progressively with the FlexRay communication cycles. When it detected other node send the NM-Vote message in order to keep network waking up, the value of FrNmReadySleepCnt will be re-initialized. When the NM period is end, if FrNmReadySleepCnt<1, then NM mode will transfer to Bus-Sleep mode. If FrNmReadySleepCnt is not overflowed all along, the node is continuing to send NM message, NM state will transfer to Normal Operation state.

The time that the node is entering the Sleep state can be calculated by the formula 1:

\[ T = \text{FrNmReadySleepCnt} \times \text{Repetition Cycle} \times \text{Vote Cycle} \times \text{FlexRay Cycle} \]  

For instance:
FrNmReadySleepCnt = 3
Repetition Cycle=4
Vote Cycle=1
FlexRay Cycle=5 msec
Then it can be calculated that the time is 3*4*1*5 msec=60 msec

3.1. Network Management Data Format

Definition of FlexRay

The node can transmit the NM-Vote message and NM-Data message individually in the NM mode, it can also transmit the NMPDU message which combined complete with NM-Vote and NM-Data, which provides a great convenience for the network management data schedule, the NMPDU format shows by Table 1.

3.2. Network Management Message and Network Schedule Design

The network data unit is generally sent in the message through static frame or dynamic frame. The form of NMPDU mapped into the message shows by Table 2.
The FlexRay network management achieves by the periodic network management messages, so it is necessary to design a schedule list for periodical communication.

According to the FlexRay communication protocol, each first slot of dynamic segment can also ensure that messages should be sent periodically in the FlexRay communication cycle. If it is multiple nodes that need to send messages periodically in the first slot of the dynamic segment, we need to set the same dynamic frame ID, but the communication cycle count must be different. Base on this way, the FlexRay network management messages will be sent in the dynamic segment, the other application messages in four independent driver control system are sent in the static segment to ensure that these transmit deterministically. The other large amount of application messages is not described in this paper. Communication schedule shows in Table 3. Application messages are sent in static slots 1-50, the network management messages sent on the first slot (51) of dynamic segment. The communication cycle of the five network management message is 0-4.

4. Design of Simulation System

According to the design of the previous section FlexRay communication network and network management, Network database is established by the FlexRay Network design tool designed by Vector company. The database is imported into the CANoe.FlexRay, network parameters of the network, node, message, signal, etc is identified by the tool, then the network can work in the simulation state.

4.1. Design of Test Panel

The test panel is human-computer interaction interface, it can simulate external IO of a node, display the node status information. The test Panel is shown in Fig. 5. The left three lights indicate the current state of network management of a node, the switch is used to simulate the network request of a node. If a lost node of network was found by other nodes, the flashing red light will indicate that one node is lost.

![Fig. 5. Test panel.](image)

4.2. Design of Network Management Function

The network management messages are sent and received by running function program. The functions are shown in Table 4.

Table 4. Design of API function.

<table>
<thead>
<tr>
<th>Categories</th>
<th>Functions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Network management and control</td>

<td>void FrNm_PduRxInd(DWORD slotId, DWORD identifier, long bRepeatMessageBit, BYTE data[]); Void FrNm_PreSendInd(DWORD dchInOut[], BYTE data[]);</td>
</tr>
</tbody>
</table>
4.3. Sending of Network Management Message

All nodes in the network should send network management messages to keep the network awake in network mode. It can be traced the network management messages each node sends in the Trace window of CANoe. FlexRay as shown in Fig. 6. The ID of network Management massages are 51, but the cycle of them are different.

4.4. Bus Sleep

When all the nodes in the network don't need the communication, all nodes are in sleep state. According to the protocol, the follow tests are done:

1) Some nodes need the network communication, and some nodes don’t need the network communication. As shown in Fig. 7, network Request button of Node RR, FR, FL is pressed to indicate that the node need network communication, network Request button of Node FL is not pressed to indicated that the node doesn’t need network communication. Network management state of every node is in network mode, none of them is in Bus-Sleep Mode.

2) All nodes in the network don’t need network the communication. As shown in Fig. 8, all nodes in the network don’t need the communication, the network management of all nodes are in Bus-Sleep Mode (Fig. 9).

The network management messages of all nodes as shown in CANoe.FlexRay Trace window indicate that all nodes have stopped sending network management messages.

4.5. Wake Up the Network

If any node in the NM-cluster requires network communication, then it can wake-up the node from the Bus-Sleep Mode by transmitting Network Management-Vote messages (Fig.10). Other node which received the wake-up message, the node was awaked. VCU node sent network management message in 106.883278 s to indicate network communication, other node was waked up after receiving the network management vote. And it started to send network management message, the state of network management changed into network mode.

Fig. 7. A node request bus sleep.

Fig. 8. All nodes turn off network communication.

Fig. 9. Network management message in sleep progress.

Fig. 10. Trace window of wake up.
5. Simulation Results

Nodes’ online monitoring is an important function of network management, requiring the other nodes to discover the dropping node on the network.

Showing in Fig. 11, to shield of the FR node and then running network on simulation condition. Now pressing the RR node’s RepeatMessage button, to monitor whether there are nodes on the network have dropped. You can see that there are nodes dropped and the indicator turns red and starts flashing, indicating that the node found one node have dropped.

![Fig. 11. Node Online detected.](image)

We can see from the trace window, there are only four NM messages, the FR node which is shielded doesn’t send the NM Message (Fig. 12).

![Fig. 12. Trace window of online monitor.](image)

6. Conclusions

This paper has analyzed FlexRay communication protocol and the AUTOSAR FlexRay Network Management Principle, designed the network management database parameters for the four wheels independent driver control system, simulated the system by the CANoe. FlexRay software tools, the simulation results show that can be achieved network management functions. This network management has applied in the electric vehicle motor drive system by hardware in the loop system, which has also achieved good results.
